State: $(x, \dot{x}) \in [-1.2; 0.6] \times [-0.07; 0.07]$

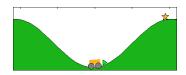

Actions : $A = \{-1, 0, 1\}$:

full speed backwards / do nothing / full speed forward

Reward: always -1 except in the terminal (goal) state $x_{\star} = 0.6$

Dynamics : when doing action a_t in state $s_t = (x_t, v_t)$, the next state $s_{t+1} = (x_{t+1}, v_{t+1})$ is

$$\left\{ \begin{array}{ll} v_{t+1} & = & \max\{\min\{v_t + \epsilon_t + 0.001a_t - 0.0025\cos(3x_t), 0.07\}, -0.07\}, \\ x_{t+1} & = & \max\{\min\{x_t + v_t, 0.6\}, -1.2\}. \end{array} \right.$$

State: $(x, \dot{x}) \in [-1.2; 0.6] \times [-0.07; 0.07]$

Actions : $A = \{-1, 0, 1\}$:

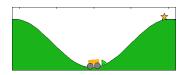

full speed backwards / do nothing / full speed forward

Reward: always -1 except in the terminal (goal) state $x_{\star} = 0.6$

Dynamics : when doing action a_t in state $s_t = (x_t, v_t)$, the next state $s_{t+1} = (x_{t+1}, v_{t+1})$ is

$$\left\{ \begin{array}{lll} v_{t+1} & = & \max\{\min\{v_t+\epsilon_t+0.001a_t-0.0025\cos(3x_t),0.07\},-0.07\},\\ x_{t+1} & = & \max\{\min\{x_t+v_t,0.6\},-1.2\}. \end{array} \right.$$

→ for physicists, this may be "continuous space, known dynamics"

State: $(x, \dot{x}) \in [-1.2; 0.6] \times [-0.07; 0.07]$

Actions : $A = \{-1, 0, 1\}$:

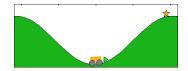

full speed backwards / do nothing / full speed forward

Reward: always -1 except in the terminal (goal) state $x_{\star} = 0.6$

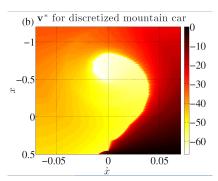

Dynamics : when doing action a_t in state $s_t = (x_t, v_t)$, the next state $s_{t+1} = (x_{t+1}, v_{t+1})$ is

$$\left\{ \begin{array}{lll} v_{t+1} & = & \max\{\min\{v_t+\epsilon_t+0.001a_t-0.0025\cos(3x_t),0.07\},-0.07\},\\ x_{t+1} & = & \max\{\min\{x_t+v_t,0.6\},-1.2\}. \end{array} \right.$$

→ for others, this is a "continuous space, unknown dynamics" setting

The optimal policy is to first climb up the other side :

More "Large space, Unknown Dynamics"

Many concrete problems where RL could be applied fall in this framework

- micro-grid management
- self-driving cars
- autonomous robotics . . .

Benchmarks often used by researcher these days are video games :

- dynamics may be unknown (enemies behavior, random level generation...)
- → state-space may be large (e.g., pixels)

Outline

- 1 From Values to Policy Learning
- 2 Policy Evaluation with Approximation

- 3 Learning the Optimal Policy : Approximate Dynamic Programming
- 4 Learning the Optimal Policy : Approximate Q-Learning

Learning Values or Q-Values

In RL, one often learn values instead of policy directly :

$$V^{\star}(s) = \max_{\pi} \left. \mathbb{E}^{\pi} \left[\left. \sum_{t=1}^{\infty} \gamma^{t-1} r_{t} \right| s_{1} = s
ight]$$

Property: $V^*(s) = \max_a Q^*(s, a)$.

From an estimate of V^* to an estimate of Q^*

$$Q \qquad \xrightarrow{\text{easy}} \qquad V(s) = \max_{a} Q(s, a)$$

$$V \stackrel{ ext{possibly harder}}{\longrightarrow} Q(s, a) = r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} \left[V(s) \right]$$

The policy deduced from an estimate V is $\pi = \text{greedy}(V)$

$$\pi(s) = \underset{a \in \mathcal{A}}{\operatorname{argmax}} \left(r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} \left[V(s') \right] \right)$$

 \rightarrow decide when to approximate V^* or Q^*

Learning Values or Q-Values

In RL, one often learn values instead of policy directly :

$$Q^{\star}(s,a) = \max_{\pi} \left. \mathbb{E}^{\pi} \left[\left. \sum_{t=1}^{\infty} \gamma^{t-1} r_{t} \right| s_{1} = s, a_{1} = a
ight]
ight.$$

Property: $V^*(s) = \max_a Q^*(s, a)$.

From an estimate of V^* to an estimate of Q^*

$$Q \xrightarrow{\text{easy}} V(s) = \max_{a} Q(s, a)$$
V possibly harder $Q(s, a) = \sqrt{s}$

$$V \stackrel{ ext{possibly harder}}{\longrightarrow} Q(s, a) = r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} \left[V(s)
ight]$$

The policy deduced from an estimate V is $\pi = \operatorname{greedy}(V)$

$$\pi(s) = \underset{a \in \mathcal{A}}{\operatorname{argmax}} \left(r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} \left[V(s') \right] \right)$$

 \rightarrow decide when to approximate V^* or Q^*

Learning Values or Q-Values

In RL, one often learn values instead of policy directly :

$$Q^{\star}(s,a) = \max_{\pi} \left. \mathbb{E}^{\pi} \left[\left. \sum_{t=1}^{\infty} \gamma^{t-1} r_{t} \right| s_{1} = s, a_{1} = a \right] \right.$$

Property: $V^*(s) = \max_a Q^*(s, a)$.

From an estimate of V^* to an estimate of Q^*

$$egin{aligned} Q & \stackrel{\mathsf{easy}}{\longrightarrow} & V(s) = \max_{a} Q(s,a) \ V & \stackrel{\mathsf{possibly harder}}{\longrightarrow} & Q(s,a) = r(s,a) + \gamma \mathbb{E}_{s' \sim p(\cdot \mid s,a)} \left[V(s)
ight] \end{aligned}$$

The policy deduced from an estimate Q is $\pi = \operatorname{greedy}(Q)$

$$\pi(s) = \underset{a \in A}{\operatorname{argmax}} Q(s, a)$$

 \rightarrow decide when to approximate V^* or Q^*

From Values to Policies

Question : how does the approximation error $\|V - V^*\|$ impact the performance loss of the policy deduced from V?

Proposition

Let V be an approximation of V^* and $\pi = \operatorname{greedy}(V)$.

$$\underbrace{\|V^\star - V^\pi\|_\infty}_{\text{performance loss}} \leq \frac{2\gamma}{1-\gamma} \underbrace{\|V^\star - V\|_\infty}_{\text{approximation error}}.$$

▶ also,
$$||V^* - V||_{\infty} \le ||Q^* - Q||_{\infty}$$
 if $V(s) = \max_a Q(s, a)$.

Proof.

Consequence: Revisiting Value Iteration

Algorithm 1: Value Iteration

```
Input : \epsilon = stopping parameter
               V_0 = \text{any function (e.g. } V_0 \leftarrow 0_S)
1 V \leftarrow V_0
2 while ||V - T^*(V)||_{\infty} \ge \epsilon do
   V \leftarrow T^*(V)
```

4 end

Return: $\hat{pi} = \text{greedy}(V)$

Exercise:

- Prove that if $VI(\varepsilon)$ stops after iteration k, $||V_k V^*||_{\infty} \leq \frac{\varepsilon}{1-\alpha}$
- Prove that the number of steps before stopping is at most $\log(||V_0 - V_1||) / \log(1/\gamma)$
- **3** With what value ε' should we run $VI(\varepsilon')$ so that it output a policy $\hat{\pi}$ satisfying $\|V^{\hat{\pi}} - V^{\star}\|_{\infty} \leq \varepsilon$. How many iterations does it need?

Value Functions Approximation

Problem : Often \mathcal{S} is too large to store a vector $V \in \mathbb{R}^S$ or a table $Q \in \mathbb{R}^{S \times A}$ in memory...

Solution : look for estimates V (resp. Q) of V^* (resp. Q^*) in an approximation space \mathcal{F}_V (resp. \mathcal{F}_Q)

$$\mathcal{F}_{V} \subseteq \mathcal{F}(\mathcal{S}, \mathbb{R})$$
 $\mathcal{F}_{\mathcal{O}} \subseteq \mathcal{F}(\mathcal{S} \times \mathcal{A}, \mathbb{R})$

Parametric approximation :

$${\mathcal F}_V = \Big\{ s \mapsto V_ heta(s) \; ig| \; heta \in \Theta \Big\} \quad {\mathcal F}_Q = \Big\{ (s,a) \mapsto Q_ heta(s,a) \; ig| \; heta \in \Theta \Big\}$$

 \Rightarrow only requires to store a parameter θ (typically in \mathbb{R}^d with $d \ll |\mathcal{S}|$)

Smooth parameterization if $\nabla_{\theta} V_{\theta}(s)$ (resp. $\nabla_{\theta} Q_{\theta}(s, a)$) can be computed

Value Functions Approximation

Problem : Often S is too large to store a vector $V \in \mathbb{R}^S$ or a table $Q \in \mathbb{R}^{S \times A}$ in memory...

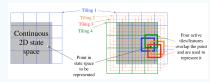

Solution : look for estimates V (resp. Q) of V^* (resp. Q^*) in an approximation space \mathcal{F}_V (resp. \mathcal{F}_Q)

$$\mathcal{F}_{V} \subseteq \mathcal{F}(\mathcal{S}, \mathbb{R})$$
 $\mathcal{F}_{Q} \subseteq \mathcal{F}(\mathcal{S} \times \mathcal{A}, \mathbb{R})$

- ► Non-parametric approximation :
 - → nearest neighbors
 - → kernel smoothing

$$V_n(s) = \sum_{t=1}^n v_t \frac{K(x, s_t)}{\sum_{\ell=1}^n K(x, s_\ell)}$$
 for some kernel K

→ tile coding

Linear function approximation

V is some linear combinations of *basis functions* (or *features*).

$$\mathcal{F}_V = \left\{ s \mapsto V_{ heta}(s) = \sum_{i=1}^d heta_i \phi_i(s) \; \middle| \; \theta \in \mathbb{R}^d
ight\}$$

Introducing the feature vector of a state s

$$\phi(s) = (\phi_1(s), \dots, \phi_d(s))^{\top} \in \mathbb{R}^d$$

one can write

$$V_{\theta}(s) = \theta^{\top} \phi(s).$$

Remarks:

- ightharpoonup smooth parameterization with $\nabla_{\theta} V_{\theta}(s) = \phi(s)$
- if $S = \{s_1, \dots, s_S\}$, one recovers the tabular case with $\phi_i(s) = \mathbb{1}(s = s_i)$ for $i = 1, \dots, S$

Linear function approximation

Q is some linear combinations of basis functions (or features).

$$\mathcal{F}_Q = \left\{ (s, a) \mapsto Q_ heta(s, a) = \sum_{i=1}^d heta_i \phi_i(s, a) \; \middle| \; \; heta \in \mathbb{R}^d
ight\}$$

Introducing the feature vector of a state-action pair (s, a)

$$\phi(s, a) = (\phi_1(s, a), \dots, \phi_d(s, a))^{\top} \in \mathbb{R}^d$$

one can write

$$Q_{\theta}(s, a) = \theta^{\top} \phi(s, a).$$

Remarks:

- ightharpoonup smooth parameterization with $\nabla_{\theta} Q_{\theta}(s,a) = \phi(s,a)$
- ▶ if $S = \{s_1, ..., s_S\}$, $A = \{a_1, ..., a_A\}$ one recovers the tabular case with $\phi_{i,i}(s,a) = \mathbb{1}(s = s_i, a = a_i)$ for i = 1, ..., S and j = 1, ..., A

Examples of features

- $ightharpoonup \mathcal{S} \subseteq \mathbb{R}$: one may use polynomial or Fourrier basis
- \triangleright $S = \mathcal{I}_1 \times \cdots \times \mathcal{I}_K$: one may use tensor products of features

$$\phi_{(i_1,\ldots,i_K)}\left(\left(s^{(1)},\ldots,s^{(K)}\right)\right) = \prod_{j=1}^K \phi_{i_j}\left(s^{(j)}\right)$$

RBF features

If $\mathcal{S} \subseteq \mathbb{R}^d$, one can use Radial Basic Functions

$$\phi_i(s) = \exp\left(-\eta \|s - s^{(i)}\|^2\right),\,$$

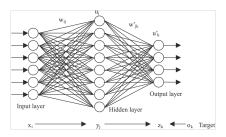

with some scale parameter η and "centers" $s^{(1)}, \ldots, s^{(d)}$ (e.g. a uniform covering of S, or random centers)

Non linear function approximation

Linear function approximation requires to design (meaningful) features, which can be hard...

Modeling V as a neural network can be more powerful :

- neural networks are known to be universal approximators
- ▶ they "learn features" from the data
- ▶ and $\nabla_{\theta} V_{\theta}(s)$ can still be computed efficiently

Outline

1 From Values to Policy Learning

2 Policy Evaluation with Approximation

3 Learning the Optimal Policy : Approximate Dynamic Programming

4 Learning the Optimal Policy : Approximate Q-Learning

Performance measure

In the tabular case, we proposed algorithms that converge to the **exact** V^{π} . This is in general hopeless with function approximation.

→ we can instead try to minimize the Mean Square Error

Mean Square Value Error

Let ν be some probability measure on the state space \mathcal{S} and $V: \mathcal{S} \to \mathbb{R}$.

$$exttt{MSVE}_
u(V) = \mathbb{E}_{s \sim
u} \left[\left(V^\pi(s) - V(s)
ight)^2
ight]$$

Performance measure

In the tabular case, we proposed algorithms that converge to the **exact** V^{π} . This is in general hopeless with function approximation.

→ we can instead try to minimize the Mean Square Error

Mean Square Value Error

Let ν be some probability measure on the state space \mathcal{S} and $V: \mathcal{S} \to \mathbb{R}$.

$$ext{MSVE}_{
u}(V) = \mathbb{E}_{s \sim
u} \left[\left(V^{\pi}(s) - V(s)
ight)^2
ight]$$

 \rightarrow what measure ν do we choose?

Assumption. Under the policy π , the sequence of visited state $(s_t)_{t\in\mathbb{N}}$ is a Markov chain. We assume that it admits a stationary distribution ν .

Performance measure

We proposed before algorithms that converge to the **exact** V^{π} . This is in general hopeless with function approximation.

→ we can instead try to minimize the Mean Square Error

Mean Square Value Error

Let ν be some probability measure on the state space \mathcal{S} and $V: \mathcal{S} \to \mathbb{R}$.

$$exttt{MSVE}_{
u}(V) = \mathbb{E}_{s \sim
u} \left[(V^{\pi}(s) - V(s))^2
ight]$$

Remark : defining $||\cdot||_{\nu}$ to be the norm associated to the scalar product

$$\langle f|g\rangle_{\nu}=\mathbb{E}_{s\sim\nu}\left[f(s)g(s)\right],$$

one has

$$MSVE_{\nu}(V) = ||V^{\pi} - V||_{\nu}^{2}$$

Minimizing the MSVE

We consider a smooth parametric representation for V, $\mathcal{F} = \{V_{\theta}, \theta \in \Theta\}$, for which we can define

$$exttt{MSVE}(heta) = \mathbb{E}_{
u}\left[\left(V^{\pi}(s) - V_{ heta}(s)
ight)^2
ight]$$

and we aim for $\theta^* = \operatorname{argmin}_{\theta \in \Theta} MSVE(\theta)$.

Given the smooth parameterization, one can compute

$$abla_{ heta} ext{MSVE}(heta) = -2 \mathbb{E}_{
u} \left[\left(V^{\pi}(s) - V_{ heta}(s)
ight)
abla_{ heta} V_{ heta}(s)
ight]$$

(valid for finite state space, and possibly under some assumption in continuous state spaces)

Gradient descent:

$$\theta_t \leftarrow \theta_{t-1} + \alpha_t \times \mathbb{E}_{\nu} \left[\left(V^{\pi}(s) - V_{\theta_{t-1}}(s) \right) \nabla_{\theta} V_{\theta_{t-1}}(s) \right]$$

Minimizing the MSVE

We consider a smooth parametric representation for V, $\mathcal{F} = \{V_{\theta}, \theta \in \Theta\}$, for which we can define

$$exttt{MSVE}(heta) = \mathbb{E}_{
u} \left[\left(V^{\pi}(s) - V_{ heta}(s)
ight)^2
ight]$$

and we aim for $\theta^* = \operatorname{argmin}_{\theta \in \Theta} \text{MSVE}(\theta)$.

Given the smooth parameterization, one can compute

$$abla_{ heta} ext{MSVE}(heta) = -2 \mathbb{E}_{
u} \left[\left(V^{\pi}(s) - V_{ heta}(s) \right)
abla_{ heta} V_{ heta}(s)
ight]$$

(valid for finite state space, and possibly under some assumption in continuous state spaces)

Stochastic gradient descent :

$$\theta_t \leftarrow \theta_{t-1} + \alpha_t \times (V^{\pi}(s_t) - V_{\theta_{t-1}}(s_t)) \nabla_{\theta} V_{\theta_{t-1}}(s_t)$$

(for large t, s_t is approximately distributed under ν)

Minimizing the MSVE

We consider a smooth parametric representation for V, $\mathcal{F} = \{V_{\theta}, \theta \in \Theta\}$, for which we can define

$$exttt{MSVE}(heta) = \mathbb{E}_{
u} \left[\left(V^{\pi}(s) - V_{ heta}(s)
ight)^2
ight]$$

and we aim for $\theta^* = \operatorname{argmin}_{\theta \in \Theta} MSVE(\theta)$.

Given the smooth parameterization, one can compute

$$abla_{ heta} ext{MSVE}(heta) = -2 \mathbb{E}_{
u} \left[\left(V^{\pi}(s) - V_{ heta}(s)
ight)
abla_{ heta} V_{ heta}(s)
ight]$$

(valid for finite state space, and possibly under some assumption in continuous state spaces)

Stochastic gradient descent :

$$\theta_t \leftarrow \theta_{t-1} + \alpha_t \times \left(V^{\pi}(s_t) - V_{\theta_{t-1}}(s_t) \right) \nabla_{\theta} V_{\theta_{t-1}}(s_t)$$

(for large t, s_t is approximately distributed under ν)

$$\rightarrow$$
 problem : $V^{\pi}(s_t)$ is unknown...

A semi-gradient approach

Idea: in the stochastic gradient descent update

$$\theta_t \leftarrow \theta_{t-1} + \alpha_t \times \left(V^{\pi}(s_t) - V_{\theta_{t-1}}(s_t)\right) \nabla_{\theta} V_{\theta_{t-1}}(s_t)$$

replace $V^{\pi}(s_t)$ by either

- ▶ a Monte-Carlo estimate (TD(1))
- a "Bootstrap" estimate (TD(0))

TD(0) with smooth function approximation

The TD(0) semi-gradient update is

$$\theta_t \leftarrow \theta_{t-1} + \alpha_t \times (r_t + \gamma V_{\theta_{t-1}}(s_{t+1}) - V_{\theta_{t-1}}(s_t)) \nabla_{\theta} V_{\theta_{t-1}}(s_t)$$

↑ this is *not* a stochastic gradient update, hence the terminology

- → stepsize tuning : decaying not too fast (Robbins-Monro style)
- → very few convergence guarantees besides the linear case...

$\mathsf{TD}(0)$ with linear function approximation

We assume $V_{\theta}(s) = \theta^{\top} \phi(s)$ with the feature vector

$$\phi(s) = (\phi_1(s), \dots, \phi_d(s))^{\top} \in \mathbb{R}^d.$$

Then $\nabla_{\theta} V_{\theta}(s) = \phi(s)$ and the algorithm becomes

TD(0) with linear function approximation

Along a trajectory following π , after observing (s_t, r_t, s_{t+1}) update

$$\theta_t = \theta_{t-1} + \alpha_t \left(r_t + \gamma \theta_{t-1}^{\top} \phi(s_{t+1}) - \theta_{t-1}^{\top} \phi(s_t) \right) \phi(s_t).$$

Using the notation $\phi_t = \phi(s_t)$, one has

$$\theta_t = \theta_{t-1} + \alpha_t \left(r_t \phi_t - \phi_t (\phi_t - \gamma \phi_{t+1})^\top \theta_{t-1} \right).$$

Convergence properties

Theorem

Under the following assumptions:

- **1** the Markov chain $(s_t)_{t\in\mathbb{N}}$ admits a stationary distribution ν
- ② the state space is finite and the vectors $\phi_i = (\phi_i(s))_{s \in S} \in \mathbb{R}^S$ are linearly independent
- 1 the step-sizes satisfy the Robbins-Monro conditions, i.e.

$$\sum_{t=1}^{\infty} \alpha_t = \infty \ \ \text{and} \ \ \sum_{t=1}^{\infty} \alpha_t < \infty$$

then the parameter θ_t converges almost surely to some value θ_{TD} s.t.

$$V_{ heta_{ exttt{TD}}} = \underbrace{igcap_{ extstyle \mathcal{F},
u} \mathcal{T}^{\pi}}_{ ext{projected}} V_{ heta_{ exttt{TD}}}$$

$$\Pi_{\mathcal{F},\nu} T^{\pi}(V) = \operatorname*{argmin}_{f \in \mathcal{F}} ||T^{\pi}(V) - f||_{\nu}$$

Computing the fixed point

According to the theorem, TD(0) converges to the solution to

$$V_{ heta_{ exttt{TD}}} = \Pi_{\mathcal{F},
u} \, T^\pi \, V_{ heta_{ exttt{TD}}}$$

Proposition

The vector $\theta_{\mathtt{TD}}$ can be obtained as a solution to the linear system

$$A^{\pi}\theta_{TD}=b^{\pi},$$

where

$$A^{\pi} = \mathbb{E}_{\substack{s \sim \nu \\ s' \sim p(\cdot \mid s, \pi(s))}} \left[\phi(s) \left(\phi(s) - \gamma \phi(s') \right)^{\top} \right] \in \mathbb{R}^{d \times d}$$

$$b^{\pi} = \mathbb{E}_{s \sim \nu} \left[r(s, \pi(s)) \phi(s) \right] \in \mathbb{R}^{d}$$

Proof.

Why does TD(0) converge to θ_{TD} ?

(heuristic argument in [Sutton and Barto, 1998])

Recall the TD(0) update :

$$\theta_t = \theta_{t-1} + \alpha_t \left(r_t \phi(s_t) - \phi(s_t) (\phi(s_t) - \gamma \phi(s_{t+1}))^\top \theta_{t-1} \right)$$

= $\theta_{t-1} + \alpha_t \left(b_t - A_t \theta_{t-1} \right),$

where we introduce

$$A_t = \phi(s_t)(\phi(s_t) - \gamma \phi(s_{t+1}))^{\top} \in \mathbb{R}^{d \times d}$$

$$b_t = r_t \phi(s_t) \in \mathbb{R}^d$$

Why does TD(0) converge to θ_{TD} ?

(heuristic argument in [Sutton and Barto, 1998])

Recall the TD(0) update :

$$\theta_t = \theta_{t-1} + \alpha_t \left(r_t \phi(s_t) - \phi(s_t) (\phi(s_t) - \gamma \phi(s_{t+1}))^\top \theta_{t-1} \right)$$

= $\theta_{t-1} + \alpha_t \left(b_t - A_t \theta_{t-1} \right),$

where we introduce

$$A_t \simeq \mathbb{E}_{s_t \sim \nu} \left[\phi(s_t) (\phi(s_t) - \gamma \phi(s_{t+1}))^\top \right] = A^{\pi}$$

$$b_t \simeq \mathbb{E}_{s_t \sim \nu} \left[r_t \phi(s_t) \right] = b^{\pi}$$

when t is large as s_t is approximately drawn under ν .

Why does TD(0) converge to θ_{TD} ?

(heuristic argument in [Sutton and Barto, 1998])

Recall the TD(0) update:

$$\theta_t = \theta_{t-1} + \alpha_t \left(r_t \phi(s_t) - \phi(s_t) (\phi(s_t) - \gamma \phi(s_{t+1}))^\top \theta_{t-1} \right)$$

= $\theta_{t-1} + \alpha_t \left(b_t - A_t \theta_{t-1} \right),$

where we introduce

$$A_t \simeq \mathbb{E}_{s_t \sim \nu} \left[\phi(s_t) (\phi(s_t) - \gamma \phi(s_{t+1}))^\top \right] = A^{\pi}$$

$$b_t \simeq \mathbb{E}_{s_t \sim \nu} \left[r_t \phi(s_t) \right] = b^{\pi}$$

when t is large as s_t is approximately drawn under ν .

Approximate recursion:

$$\theta_t = \theta_{t-1} + \alpha \left(b^{\pi} - A^{\pi} \theta_{t-1} \right)$$

If it converges, the convergence is towards a fixed point, satisfying

$$b^{\pi} - A^{\pi}\theta = 0$$

Least Square Temporal Difference

Idea: Now that we know towards what TD(0) converges, is there a way to get there faster?

$$A^{\pi}\theta_{TD}=b^{\pi}$$
,

where

$$A^{\pi} = \mathbb{E}_{\substack{s \sim \nu \\ s' \sim p(\cdot | s, \pi(s))}} \left[\phi(s) \left(\phi(s) - \gamma \phi(s') \right)^{\top} \right] \in \mathbb{R}^{d \times d}$$

$$b^{\pi} = \mathbb{E}_{s \sim \nu} \left[r(s, \pi(s)) \phi(s) \right] \in \mathbb{R}^{d}$$

use estimation :

$$\hat{A}_n = \frac{1}{n} \sum_{t=1}^n \phi(s_t) \left(\phi(s_t) - \gamma \phi(s_{t+1}) \right)^\top \quad \text{and} \quad \hat{b}_n = \frac{1}{n} \sum_{t=1}^n r_t \phi(s_t)$$

If \hat{A}_n is invertible, $\hat{\theta}_n = \hat{A}_n^{-1}\hat{b}_n$.

An online implementation of LSTD

We need to compute

$$\hat{\theta}_n = \hat{A}_n^{-1} \hat{b}_n$$

where

$$\hat{A}_n = \sum_{t=1}^n \phi(s_t) \left(\phi(s_t) - \gamma \phi(s_{t+1}) \right)^\top \quad \text{and} \quad \hat{b}_n = \sum_{t=1}^n r_t \phi(s_t).$$

→ requires to invert a d × d matrix at every round... (much more costly than the TD(0) update!)

More efficient: update the inverse online!

Sherman-Morrison formula

For any matrix $B \in \mathbb{R}^{d \times d}$ and vectors $u, v \in \mathbb{R}^d$,

$$(B + uv^{\top})^{-1} = B^{-1} - \frac{B^{-1}uv^{\top}B^{-1}}{1 + v^{\top}B^{-1}u}$$

LSTD update versus TD(0) update

Letting $\phi_t = \phi(s_t)$, both update also rely on temporal differences

$$\delta_t(\theta) = r_t + \gamma \phi_{t+1}^\top \theta - \phi_t^\top \theta$$

Recursive LSTD

$$C_{n} = C_{n-1} - \frac{C_{n-1}\phi_{n}(\phi_{n} - \gamma\phi_{n+1})^{\top}C_{n-1}}{1 + (\phi_{n} - \gamma\phi_{n+1})^{\top}C_{n-1}\phi_{n}}$$

$$\theta_{n} = \theta_{n-1} + \frac{C_{n-1}}{1 + (\phi_{n} - \gamma\phi_{n+1})^{\top}C_{n-1}\phi_{n}}\delta_{n}(\theta_{n-1})\phi_{n}$$

TD(0)

$$\theta_n = \theta_{n-1} + \alpha_n \delta_n(\theta_{n-1}) \phi_n$$

Complexity: $O(d^2)$ versus O(1) but LSTD converges faster

Wait... How good is the TD solution?

We presented two algorithms which converge to the value function

$$V_{ exttt{TD}}(s) = heta_{ exttt{TD}}^ op \phi(s)$$

such that V_{TD} is a fixed point to $\Pi_{\mathcal{F},\nu}T^{\pi}$ (when it exists).

 \rightarrow Is it at all close to our target V^{π} ?

Proposition

If ν is the stationary distribution of the sequence of states

- ▶ $\Pi_{\mathcal{F},\nu} T^{\pi}$ is a γ contraction with respect to $||\cdot||_{\nu}$ and admits therefore a unique fixed point, V_{TD}
- The TD solution satisfies

$$\left|\left|V^{\pi}-V_{\mathtt{TD}}\right|\right|_{
u} \leq rac{1}{\sqrt{1-\gamma^2}}\inf_{V \in \mathcal{F}}\left|\left|V^{\pi}-V
ight|\right|_{
u}$$

Answer: not too far from the best possible approximation (wrt to $||\cdot||_{\nu}$)

Outline

1 From Values to Policy Learning

- 2 Policy Evaluation with Approximation
- 3 Learning the Optimal Policy : Approximate Dynamic Programming

4 Learning the Optimal Policy : Approximate Q-Learning

Reminder: Policy Iteration

- Let π_0 be any stationary policy
- **2** At each iteration k = 1, 2, ..., K
 - → Policy evaluation : given π_{k-1} , compute $V_k = V^{\pi_{k-1}}$.
 - → Policy improvement : compute the *greedy* policy

$$\pi_k(s) \in \operatorname*{argmax}_{a \in \mathcal{A}} \big[r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} [V_{k-1}(s')] \big].$$

3 Return the last policy π_K

Reminder: Policy Iteration

- Let π_0 be any stationary policy
- **2** At each iteration k = 1, 2, ..., K
 - → Policy evaluation : given π_{k-1} , compute $V_k = V^{\pi_{k-1}}$.
 - → Policy improvement : compute the greedy policy

$$\pi_k(s) \in \operatorname*{argmax}_{a \in \mathcal{A}} \big[r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} [V_{k-1}(s')] \big].$$

- **3** Return the last policy π_K
- ► **Problem**: we saw how to approximately perform policy evaluation, how about policy improvement?

Reminder: Policy Iteration

- Let π_0 be any stationary policy
- 2 At each iteration k = 1, 2, ..., K
 - → Policy evaluation : given π_{k-1} , compute $V_k = V^{\pi_{k-1}}$.
 - → Policy improvement : compute the greedy policy

$$\pi_k(s) \in \operatorname*{argmax}_{a \in \mathcal{A}} \big[r(s, a) + \gamma \mathbb{E}_{s' \sim p(\cdot | s, a)} [V_{k-1}(s')] \big].$$

- **3** Return the last policy π_K
- ► **Problem**: we saw how to approximately perform policy evaluation, how about policy improvement?
- → work with Q-values directly to make policy improvement easy!

LSTD-Q

LSTD-Q: a variant of LSTD aimed at estimating directly Q^{π}

$$Q_{\theta}(s, a) = \theta^{\top} \phi(s, a)$$

The solution to

$$Q_{\theta} = \Pi_{\mathcal{F},\nu} T^{\pi} Q_{\theta}$$

can similarly be approximated by solving a linear system.

$$\begin{cases} A_n = A_{n-1} + \phi(s_n, a_n)(\phi(s_n, a_n) - \gamma \phi(s_{n+1}, \pi(s_{n+1})))^\top \\ b_n = b_{n-1} + \phi(s_n, a_n)r_n \end{cases}$$

$$\theta_n^{\text{LSTD-Q}} = A_n^{-1}b_n$$

→ The resulting algorithm is **Least-Squares Policy Iteration** (LSPI) [Lagoudakis and Parr, 2003]

Reminder: Value Iteration

- **1** Let Q_0 be any action-value function
- **2** At each iteration k = 1, 2, ..., K

$$Q_k(s,a) = T^*Q_{k-1}(s,a)$$

$$= r(s,a) + \mathbb{E}_{s' \sim p(\cdot|s,a)} \left[\max_{a' \in \mathcal{A}} Q_{k-1}(s',a') \right]$$

Return the greedy policy

$$\pi_{K}(s) \in \operatorname*{argmax}_{a \in A} Q_{K}(s, a).$$

Reminder: Value Iteration

- **1** Let Q_0 be any action-value function
- $extbf{2}$ At each iteration $k = 1, 2, \dots, K$

$$Q_k(s,a) = T^*Q_{k-1}(s,a)$$

$$= r(s,a) + \mathbb{E}_{s' \sim p(\cdot|s,a)} \left[\max_{a' \in \mathcal{A}} Q_{k-1}(s',a') \right]$$

Return the greedy policy

$$\pi_K(s) \in \operatorname*{argmax}_{a \in A} Q_K(s, a).$$

- **Problem**: how can we approximate T^*Q_k ?
- Problem : does value iteration still work with such an approximation?

Fitted-Q Iteration

```
Input: number of iterations K, number of samples per iteration n, Initial function Q_0 \in \mathcal{F}, sampling distribution \rho, Approximation space \mathcal{F}, loss function \ell
1 for k=1,\ldots,K do
```

```
Draw n samples (s_i, a_i) \sim \rho
Perform n transitions r_i, s_i' = \text{step}(s_i, a_i)
Compute the targets y_i = r_i + \gamma \max_a Q_{k-1}(s_i', a)
From the training dataset \mathcal{D}_k = \{((s_i, a_i), y_i)_{1 \leq i \leq n}\}, solve the empirical risk minimization problem:
f \in \underset{f \in \mathcal{F}}{\operatorname{argmin}} \ \frac{1}{n} \sum_{i=1}^{n} \ell\left(y_i, f(s_i, a_i)\right)
Set Q_k = f (with clipping if f(s, a) \notin \left[-\frac{R_{\max}}{1-\gamma}; \frac{R_{\max}}{1-\gamma}\right]).
```

8 end

Return: $\pi = \operatorname{greedy}(Q_K)$

► ERM can be replaced by other possibly non-parameteric regression techniques (decision trees, *k*-nn, . . .)

Linear Fitted Q-Iteration

```
Input: number of iterations K, number of samples per iteration n.
               Initial function Q_0 \in \mathcal{F}, sampling distribution \rho,
               Approximation space \mathcal{F}, loss function \ell
1 for k = 1, ..., K do
        Draw n samples (s_i, a_i) \sim \rho
        Perform n transitions r_i, s'_i = \text{step}(s_i, a_i)
        Compute the targets y_i = r_i + \gamma \max_a Q_{k-1}(s'_i, a)
        From the training dataset \mathcal{D}_k = \{((s_i, a_i), y_i)_{1 \le i \le n}\}, solve the
         least squares problem:
                            \theta_k \in \underset{\theta \in \mathbb{R}^d}{\operatorname{argmin}} \ \frac{1}{n} \sum_{i=1}^n (y_i - \theta^\top \phi(s_i, a_i))^2
        Set Q_k(s, a) = \theta_k^{\top} \phi(s, a) (with clipping).
8 end
```

2

3

4

5

6

Return: $\pi = \operatorname{greedy}(Q_K)$

- 33 Emilie Kaufmann | CRIStAL

Linear Fitted-Q: Sampling

- **1** Draw *n* samples $(s_i, a_i) \stackrel{\text{i.i.d}}{\sim} \rho$
- **②** Perform a transition for each of them : $s_i' \sim p(\cdot|s_i,a_i)$ and $r_i \sim \nu_{(s_i,a_i)}$

Linear Fitted-Q: Sampling

- **1** Draw *n* samples $(s_i, a_i) \stackrel{\text{i.i.d}}{\sim} \rho$
- **②** Perform a transition for each of them : $s_i' \sim p(\cdot|s_i, a_i)$ and $r_i \sim \nu_{(s_i, a_i)}$
- → In practice sampling can be done once before running the algorithm (or a database of transitions can be used)
- ightharpoonup The sampling distribution ho should cover the state-action space in all relevant regions
- → The algorithm requires call to a simulator which can simulate independent transitions from anywhere in the state-action space

Linear Fitted-Q: Building the training set

- **3** Compute $y_i = r_i + \gamma \max_a Q_{k-1}(s'_i, a)$
- $\bullet \ \, \mathsf{Build training set} \,\, \mathcal{D}_k = \{((s_i, a_i), y_i)_{1 \leq i \leq n}\}$

Linear Fitted-Q: Building the training set

- **3** Compute $y_i = r_i + \gamma \max_a Q_{k-1}(s'_i, a)$
- $\bullet \text{ Build training set } \mathcal{D}_k = \{((s_i, a_i), y_i)_{1 \leq i \leq n}\}$
- → Each sample y_i is an unbiased estimate of $T^*Q_{k-1}(s_i, a_i)$:

$$\mathbb{E}[y_{i}|s_{i}, a_{i}, Q_{k-1}] = \mathbb{E}[r_{i} + \gamma \max_{a'} Q_{k-1}(s'_{i}, a')|s_{i}, a_{i}, Q_{k-1}]$$

$$= r(s_{i}, a_{i}) + \gamma \mathbb{E}_{s' \sim p(\cdot|s_{i}, a_{i})}[\max_{a'} Q_{k-1}(s', a')]$$

$$= T^{*}Q_{k-1}(s_{i}, a_{i})$$

- → The problem "reduces" to standard regression
- → A new regression problem at each iteration : new function to fit T^*Q_{k-1} + new training set \mathcal{D}_k

Linear Fitted-Q: The regression problem

Solve the least squares problem

$$\theta_k \in \underset{\theta \in \mathbb{R}^d}{\operatorname{argmin}} \ \frac{1}{n} \sum_{i=1}^n (y_i - \theta^\top \phi(s_i, a_i))^2$$

Linear Fitted-Q: The regression problem

Solve the least squares problem

$$\theta_k \in \underset{\theta \in \mathbb{R}^d}{\operatorname{argmin}} \ \frac{1}{n} \sum_{i=1}^n (y_i - \theta^\top \phi(s_i, a_i))^2$$

→ standard linear regression problem with design matrix and targets

$$X = \begin{pmatrix} \phi(s_1, a_1)^\top \\ \phi(s_2, a_2)^\top \\ \vdots \\ \phi(s_n, a_n)^\top \end{pmatrix} \in \mathbb{R}^{n \times d} \text{ and } Y = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} \in \mathbb{R}^d$$

whose solution is

$$\theta_k = \left(X^\top X \right)^{-1} X^\top Y.$$

Linear Fitted-Q: Error bound

Theorem

Linear FQI with a space $\mathcal F$ of d features, with n samples drawn from ρ at each iteration, returns a policy π_K after K iterations which satisfies, w.p. larger than $1-\delta$,

$$\|Q^{\star} - Q^{\pi_{K}}\|_{\mu} \leq \frac{2\gamma}{(1-\gamma)^{2}} C_{\mu,\rho} \left[\sup_{g \in \mathcal{F}} \inf_{f \in \mathcal{F}} \|T^{\star}g - f\|_{\rho} + O\left(\sqrt{\frac{d \log(n/\delta)}{\omega n}}\right) \right] + O\left(\frac{\gamma^{K}}{(1-\gamma)^{2}}\right).$$

4 Learning the Optimal Policy : Approximate Q-Learning

Let's try to find θ minimizing

$$\begin{split} & \texttt{MSE}(\theta) &= & \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right)^{2} \right] \\ & \nabla_{\theta} \texttt{MSE}(\theta) &= & -2 \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right] \end{split}$$

Let's try to find θ minimizing

$$\begin{split} & \texttt{MSE}(\theta) &= & \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right)^{2} \right] \\ & \nabla_{\theta} \texttt{MSE}(\theta) &= & -2 \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right] \end{split}$$

→ gradient descent :

$$\theta \leftarrow \theta + \alpha \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right]$$

Let's try to find θ minimizing

$$\begin{split} & \texttt{MSE}(\theta) &= & \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right)^{2} \right] \\ & \nabla_{\theta} \texttt{MSE}(\theta) &= & -2 \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right] \end{split}$$

→ gradient descent :

$$\theta \leftarrow \theta + \alpha \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right]$$

 \Rightarrow stochastic gradient descent : if $(s_t, a_t) \sim \nu$,

$$\theta \leftarrow \theta + \alpha \left(Q^{\star}(s_t, a_t) - Q_{\theta}(s_t, a_t) \right) \nabla_{\theta} Q_{\theta}(s_t, a_t)$$

Let's try to find θ minimizing

$$\begin{split} & \texttt{MSE}(\theta) &= & \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right)^{2} \right] \\ & \nabla_{\theta} \texttt{MSE}(\theta) &= & -2 \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right] \end{split}$$

→ gradient descent :

$$\theta \leftarrow \theta + \alpha \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right]$$

 \Rightarrow stochastic gradient descent : if $(s_t, a_t) \sim \nu$,

$$\theta \leftarrow \theta + \alpha \left(Q^*(s_t, a_t) - Q_{\theta}(s_t, a_t) \right) \nabla_{\theta} Q_{\theta}(s_t, a_t)$$

 \rightarrow bootstrapping : given a transition (s_t, a_t, r_t, s_{t+1}) ,

$$\theta \leftarrow \theta + \alpha \left(r_t + \gamma \max_b Q_{\theta}(s_{t+1}, b) - Q_{\theta}(s_t, a_t) \right) \nabla_{\theta} Q_{\theta}(s_t, a_t)$$

Let's try to find θ minimizing

$$\begin{split} & \texttt{MSE}(\theta) &= & \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right)^{2} \right] \\ & \nabla_{\theta} \texttt{MSE}(\theta) &= & -2 \mathbb{E}_{\nu} \left[\left(Q^{\star}(s, a) - Q_{\theta}(s, a) \right) \nabla_{\theta} Q_{\theta}(s, a) \right] \end{split}$$

Q-Learning update with function approximation

Given a Q-value $Q_{\theta}(s, a)$, this **semi-gradient** update is

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

→ one recovers Q-Learning in the tabular case

Negative results

	TD(0)	LSPI	Fitted-Q	Q-Learning
Linear functions	V	~	V	*
Non-linear functions	×	×	(✓)	×

- ▶ TD(0) is known to diverge with non-linear function approximation
- ▶ Q-Learning can already diverge with linear function approximation...

(see examples in [Sutton and Barto, 1998])

Q-Learning update with function approximation

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

Alternative view : in each step t, perform one SGD step on

$$L(\theta) = \mathbb{E}_{\substack{(s,a) \sim \rho \\ (r,s') \sim \text{step}(s,a)}} \left[\left(r + \gamma \max_{b} Q_{\theta_{t-1}}(s',b) - Q_{\theta}(s,a) \right)^{2} \right]$$

where ρ is the current behavior policy.

Q-Learning update with function approximation

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

Alternative view : in each step t, perform one SGD step on

$$L(\theta) = \mathbb{E}_{\substack{(s,a) \sim \rho \\ (r,s') \sim \text{step}(s,a)}} \left[\left(r + \gamma \max_{b} Q_{\theta_{t-1}}(s',b) - Q_{\theta}(s,a) \right)^{2} \right]$$

where ρ is the current behavior policy.

Three tricks: (e.g. [Mnih et al., 2015, Hessel et al., 2018])

- → experience replay : rely on past transisions instead of the current one
- → mini-batches : rely on more than one transition
- → two learning scales : do not update the target network in every round

Q-Learning update with function approximation

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

Alternative view : in each step t, perform one SGD step on

$$L(heta) = \mathbb{E}_{\substack{(s,a) \sim \rho \ (r,s') \sim \text{step}(s,a)}} \left[\left(r + \gamma \max_b Q_{ heta_{t-1}}(s',b) - Q_{ heta}(s,a) \right)^2
ight]$$

where ρ is the current behavior policy.

Three tricks: (e.g. [Mnih et al., 2015, Hessel et al., 2018])

- → experience replay : rely on past transisions instead of the current one
- → mini-batches : rely on more than one transition
- → two learning scales : do not update the target network in every round

Q-Learning update with function approximation

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

Alternative view : in each step t, perform one SGD step on

$$L(\theta) = \mathbb{E}_{\substack{(s,a) \sim \rho \\ (r,s') \sim \text{step}(s,a)}} \left[\left(r + \gamma \max_{b} Q_{\theta_{t-1}}(s',b) - Q_{\theta}(s,a) \right)^{2} \right]$$

where ρ is the current behavior policy.

Three tricks: (e.g. [Mnih et al., 2015, Hessel et al., 2018])

- → experience replay : rely on past transisions instead of the current one
- → mini-batches : rely on more than one transition
- → two learning scales : do not update the target network in every round

Q-Learning update with function approximation

$$\left\{ \begin{array}{ll} \delta_t & = & r_t + \gamma \max_b Q_{\theta_{t-1}}(s_{t+1}, b) - Q_{\theta_{t-1}}(s_t, a_t) \\ \theta_t & = & \theta_{t-1} + \alpha_t \delta_t \nabla_{\theta} Q_{\theta_{t-1}}(s_t, a_t) \end{array} \right.$$

Alternative view : in each step t, perform one SGD step on

$$L(heta) = \mathbb{E}_{\substack{(s,a) \sim \rho \ (r,s') \sim ext{step}(s,a)}} \left[\left(r + \gamma \max_b Q_{ heta_{t-1}}(s',b) - Q_{ heta}(s,a)
ight)^2
ight]$$

where ρ is the current behavior policy.

Three tricks: (e.g. [Mnih et al., 2015, Hessel et al., 2018])

- → experience replay : rely on past transisions instead of the current one
- → mini-batches : rely on more than one transition
- → two learning scales : do not update the target network in every round

Deep Q Networks

```
Input: number of iterations T.
   minimatch size B, update frequency for the target network N,
  exploration sequence (\varepsilon_t), stepsize (\alpha_t)
  Initialize: replay buffer \mathcal{D} \leftarrow \{\}, first state s_1,
  online network parameter \theta, target network parameter \theta_- \leftarrow \theta
1 for t = 1, ..., T do
2
        a_t = \operatorname{argmax}_a Q_{\theta}(s_t, a) w.p. 1 - \varepsilon_t, random action w.p. \varepsilon_t
3
        Perform transition (r_t, s_{t+1}) = \text{step}(s_t, a_t)
        Add transition to the replay buffer \mathcal{D} \leftarrow \mathcal{D} \cup \{(s_t, a_t, r_t, s_{t+1})\}
4
        Draw a minibatch \mathcal{B} of size \mathcal{B} uniformly from \mathcal{D}
5
6
        Perform one step of online optimization on the loss function
                      L(\theta) = \sum_{a} \left( r + \gamma \max_{b} Q_{\theta}(s', b) - Q_{\theta}(s, a) \right)^{2}
                                (s.a,r,s') \in \mathcal{B}
       e.g. \theta \leftarrow \theta - \alpha_t \nabla_{\theta} L(\theta)
8
        every N time steps, \theta^- \leftarrow \theta
```

10 end

Return: Q_{θ}

Results on Atari Games

DQN was proposed in combination with

- ▶ a well chosen pre-processing of the state
- an optimized architecture for the Deep Neural Network used for the approximator

that reaches super-human level performance on Atari games.

Summary

In this class, we mostly saw how to scale up reinforcement learning with Value-based methods:

- ► Fitted-Q Iteration
- ► Deep Q Networks

In the sequel, we will see:

- Policy-based methods (based on direct search over a policy space)
- Actor-critic methods (using both a policy and a value),

whose performance can also be "boosted" with Deep Learning.

We will also discuss the exploration issue : can we go beyond ε -greedy? (starting with very simple MDPs : multi-armed bandits)
